THE COMPANY

The Company Green Gear Trasmissioni Srl was founded with the goal and purpose to work side by side with customers to study and develop with them the most adequate solution. Thanks to our skills and experience, gained in more than twenty years, the Company guarantees high quality production at very competitive prices. Specializing in the production of power transmission equipment, the Company is able to offer the market the best technical and manufacturing solution on specific customer requirement. Although our products find particular application in rolling mills, our experience and flexibility enables us to meet the needs of any industrial field, both in terms of application, and in terms of final product quality level. The production area and offices are located in Asti (Piedmont), geographically well located: very close to suppliers, available within a radius of 200 km, and to seaports and airports for international transport.

PRODUCTION RANGE

1. UNIVERSAL SHAFTS
2. GEAR SPINDLES
3. GEAR COUPLINGS

The universal shaft enables motion transmission between driving and driven shafts, with wide working angles. The major characteristic of a universal shaft is having a transmission ratio instantly varying, when misalignment is different from zero. The transmission ratio average value however keeps uniform; to annul such variability, the connection is made by two universal joints, equalizing the angular velocity. Motion transmission is realized by a component connecting input and output shaft ends. This component is called journal cross. Generally speaking, the universal shaft operation can be distinguished into 5 single peculiarities:

1. Torque and speed
2. Possibility of changing the distance between input and output
3. Possibility of changing the angle between input and output
4. Stress for vibration
5. Torsional strength

Great part of the energy produced under these extreme operation conditions is partially absorbed by the universal shaft, and partially by the connected components.

Our universal shafts, along with a range of products covering any application of the market, offer excellent quality level, operational safety, long working life and low maintenance costs.

Especially in iron and steel field, with hard and heavy duty applications, our universal shafts are the correct choice for the following manufacturing features:

- Monolithic yoke
- Higher misalignment and minimum torsion under high loads
- Better capacity of bearing high torque loads
- Perfect design and construction of every single component
- Selected and heat treated materials
- First-rate weldings

Our universal shafts are custom-made, following the customer's requirements. They are welded by skilled personnel, who then check weldings by ultrasonic instruments, and proceed with dynamic balancing following G16 grade and DIN ISO 1940 standards. On demand, higher grade balancing can be realized. Then, the universal shafts are lubricated according to the customer's specifications and the application they are designed for, and they are finally painted.

We are able to meet every requirement by guaranteeing the best service, thanks to our flexible manufacturing process, to our full stock availability, and to our skilled collaborators.

WORKSHOP

Green Gear Trasmissioni Srl is specialized in the production of universal shafts, thanks to its executives' twenty-year wealth of experience, and ranks as a field specialist leader. Our universal shafts find their best application in the fields of steel rolling, rubber and plastic, paper, marine industry, lifting, shredding mills and drilling. Our customers are all over the world, mainly in Europe, Asia and America. We have solved application problems to many customers through manufacturing modifications and special innovative devices, currently being patented. Our target is maintaining our quality standards along with the highest technologic development, thanks to continuous research and daily studies with the best collaborators of the field, and customers' full satisfaction as the result of our serious involvement in finding the best solution.

The efforts focused on design improvement and technological innovations enable us to offer high-quality and first-rate performance universal shafts.

Our strengths are:

- Bearing longer lifetime;
- High precision in machining operations;
- High quality of balancing;

Our one of a kind sealing system assures an excellent lubrication and consequent bearing longer lifetime. The precision of splined shafts and sliding tubes is achieved by one-step broaching machines;

tooth surfaces are nitrided, so to guarantee their lifetime.

Our universal shafts are welded, checked by ultrasonic inspections and balanced within efficient manufacturing process.

Quality Program

The outstanding points of our quality program are:

- Operating under ISO 9001:2000 certification standards
- High-level managing system, with Pert and Gant diagram processing
- State of the art design and engineering instruments
- High-qualified personnel, devoted to the mutual goal of customers' complete satisfaction
- Most up-to-date instruments for manufacturing process check, along with production equipment accurately selected

SELECTION & DIMENSIONING

To select US.A and US.B universal shaft series, please follow the following procedure.
For remaining series, kindly contact us.

1. The universal shafts are selected according to their load features, calculated torques, bearing lifetime, rotation speed and working angle.

$$T_c = K T \dots \dots \dots (1)$$

(1), (2) and (3) where:
T_c = Calculated torque [Nm]
T = Nominal torque [Nm]
P_w = Motor power [kW]
P_H = Motor power [kW]
N = Rotation speed [rpm]
K = Service factor

$$T = 9550 \frac{P_w}{n} \dots \dots \dots (2)$$

2. The calculated torque is given by the following formulas **(1), (2)** or **(1), (3)**:

$$T = 7020 \frac{P_H}{n} \dots \dots \dots (3)$$

3. Generally, the universal shafts are selected following the torque to be transmitted and the expected bearing lifetime.

(4) where:
T_c = Calculated torque [Nm]
T_n = Nominal torque [Nm] (theoretically calculated, according to the following conditions, for example: shaft speed n = 10 rpm, angle β = 3° and bearing lifetime LN = 5000 hours under load).
T_f = Fatigue torque suitable for alternate loads [Nm]
T_p = Pulsating torque suitable for pulsating loads [Nm]
T_p = 1.45 T_f

4. Check the torque following the formula **(4)**:
T_c ≤ T_n or T_c ≤ T_f or T_c ≤ T_p.....(4)

5. Check the bearing lifetime following the formula **(5)**:
 $L_N = \frac{K_L}{K_1 n \beta T^{10/3}} \times 10^{10} \geq L_{min}$

6. In case the universal shaft has both horizontal and vertical misalignment, its composite misalignment is calculated by the formula **(6)**:
 $tg \beta = \sqrt{tg^2 \beta_1 + tg^2 \beta_2}$
 where β is the composite angle, β₁ is the horizontal angular misalignment and β₂ the vertical one.

7. If the flange diameter is 390 mm or smaller, the formulas **(7)** and **(8)** shall be used to check the rotation maximum speed:

$$n_{max} \leq n \beta \dots \dots \dots (7) \text{ maximum permissible speed on working angle – Figure 7.1}$$

$$n_{max} \leq n L \dots \dots \dots (8) \text{ maximum permissible speed on operating length – Figure 7.2}$$

Maximum permissible speed in relation to operating deflection angle (figure 7-1)

Maximum permissible speed in relation to operating length (figure 7-2)

SERVICE FACTORS	DRIVEN EQUIPMENT	K
LIGHT SHOCK LOAD	Generators Centrifugal pumps Ventilators Wood handling machines Belt conveyers	1.1 - 1.3
MEDIUM SHOCK LOAD	Compressor (multi cyl.) Pumps (multi cyl.) Small section mills Continuous wire mills Conveyer primary drives	1.3 - 1.8
HEAVY SHOCK LOAD	Paper machines Marine transmissions Transport roller tables Continuous tube mills Continuous working roller tables Medium section mills Compressors (single cyl.) Pumps (single cyl.) Mixers Presses Straightening machines Crane driver Ball mills	2 - 3
EXTRA HEAVY SHOCK LOAD	Crane accessory driver Crushers Reversing working roller tables Reeling drives Scale breakers Blooming stands	3 - 5
EXTREME SHOCK LOAD	Feed roller drives Plate shears	6 - 15

8. If the universal shaft speed line is higher than 7 m/s, a test of dynamic balancing is required, normally with precision class between G6.3 e G16. Complex variables may influence the grade of balancing.

- 2) L = standard length, shorter or longer lengths are available on demand.
 Lv = standard length compensation where present.
 m = weight, referred to the dimensions of the catalogue.
 mL = weight each 100 mm of tube.
 Tn = nominal torque
 Tf = fatigue torque, i.e. the permissible torque calculated on the fatigue strength under reversible loads.

COMPANION FLANGES

We can manufacture any type of companion flange, following your requirements. Generally speaking, these sleeves are grouped into 2 families, following their geometric shape:

- a. CYLINDRICAL COMPANION FLANGES
- b. FLANGED COMPANION FLANGES

Or, following the type of connection between its flange and the universal shaft one, they are divided into 5 categories:

- 1. FLANGE WITH NO KEYWAY
- 2. FLANGE WITH KEYWAY
- 3. FLANGE WITH HIRTH SERRATION (as the picture on the right)
- 4. FLANGE WITH DOG TEETH
- 5. FLANGE WITH NO KEYWAY WITH PINS ACCORDING TO DIN 15452 STANDARDS

MAX ALLOWED FINISHED BORE DIAMETER PER SIZE

7. CYLINDRICAL FINISHED
BORE WITH SHRINK FITTING
& OIL PRESSURE REMOVAL

8. FINISHED BORE WITH FLAT WEAR KEYS

INSTALLATION, MAINTENANCE & LUBRICATION

BEARINGS

The composition of the journal cross bearings is shown in Figure 1.1. Three lines of rolls (7) are axially placed inside the bearing ring (6), closed by a ring (2), a seal (3), a flat spring, and held by a seal ring (4). A composite thrustbearing disc is placed at the bearing bottom with a grease nipple outside the bearing centre (10). The bearing is held inside the yoke by a seal ring (9).

Figure 1.1

PRELIMINARY INSTRUCTIONS

Figure 2.1

If the universal shaft needs to be kept in stock for long before installation, do not remove the protection applied on the most exposed critical surfaces. If stocked outdoor, the universal shaft must be placed on supports keeping it separated from the ground, and must be protected from rain and other atmospheric events. **When moving it, insert wooden chocks in the open surfaces of the yokes, to avoid any angle misalignment and to handle safely. When transporting or lifting universal shafts, do not rope belts or chains on the tube surrounding the spline, or on the protection tube in case of telescopic universal shafts. In fact, the universal shaft may fully open, get damaged, and endanger things and people.**

Always handle and transport in horizontal position, except for universal shafts designed for specific vertical applications. See Figure 2.1 for the suitable way of lifting and handling.

INSTALLATION

The universal shaft installation shall follow its drawing specification. Drawing specifications are elaborated following the working conditions required by the customers.

If properly installed, the universal shaft shall rotate with the motor shaft simultaneously, and the full rotating system will not swing.

To this purpose, the manufacturer has adopted the following technological and engineering precautions:

- Flange yoke and bearing hole axis are on the same plane;
- The intermediate section yoke bearing holes and the intermediate shaft axis are on the same plane (See Figure 3.1);
- The journal cross axis are placed vertically and symmetrically on the same plane;

During installation, make sure the two yokes and the intermediate shaft are placed in «W» and «Z» position and that their angles β_1 and β_2 are equal (see Figure 3.3 and 3.2).

This way, any fitting side speed variation is annulled by the joint side speed variation, with consequent simultaneous rotation of the whole transmission. The following procedure is recommended for the universal shaft installation, after the alignment on the machines to be connected is done.

INSTALLATION, MAINTENANCE & LUBRICATION

COMPANION FLANGE INSTALLATION

The different types of companion flanges require different assembly procedures. Please find below the installation procedures of two different types of companion flanges:

1. With taper bore (interference fitting):
 - I. Please follow the drawing, and check: the companion flange bore diameter, the keyway and the key seat dimensions, the flange surface, the bore diameter and their distribution, and their connection interfaces, to check if they are corresponding (keyway, hirth serration, dog teeth) for proper fitting and assembly operations.
 - II. Remove any dirt from sleeve, centering and connecting shaft, and clean every fitting surface.
 - III. Fit the keyway into its seat and align with the connecting shaft.
 - IV. Uniformly heat at a temperature of 200°C, in a furnace or in oil bath to expand the hole. When heating the oil, be careful it doesn't catch fire. You may also employ a heating torch, to heat the companion flange. While heating, continuously rotate the companion flange or turn the heating torch around it. The surface temperature shall be constantly checked and must not exceed 260° C, so to avoid overheating.
 - V. Align the heated companion flange with the universal shaft keyway and fit it onto the shaft to be connected. If the universal shaft has no shoulder, prepare a lock to prevent the companion flange from sliding beyond the fitting limit. Let the companion flange cool down, before proceeding with any further operation and/or installation.
2. Fitting with no interference:
 - I. Please refer to the drawing, and check: the companion flange bore diameter, the keyway and the key seat dimensions, the flange surface, the bore diameters and their distribution, and their connection interfaces, to check if they are corresponding (keyway, hirth serration, dog teeth) for proper fitting and assembly operations.
 - II. Remove any dirt from sleeve, centering and connecting shaft, and clean every fitting surface.
 - III. Position and fit the companion flange.
 - IV. Check the roll fitting support devices are the proper ones. If any sleeve blocking or release device is present, please check their correct operation.

UNIVERSAL SHAFT INSTALLATION

Check that the yoke bearing holes in the intermediate section and the intermediate shaft axis are on the same plane (see Figure 3.1). This is an essential check.

Check that the flange dimensions, and the whole universal shaft in general, are according to the drawing. Check that the different components are in good condition, and that the retainer rings are in their seats. Clean any dirt, if present.

If the companion flange needs to be fitted onto a driving shaft, it has to be fitted onto the universal shaft first (see Figure 4.1).

If the companion flange is already fitted onto the shaft, lift the universal shaft by a steel cable or by a chain for heavy loads, hanging it by its yokes, as shown in Figures 2.1 and 4.1. This allows the flanges to move, making the operations of alignment easier. Lift the universal shaft in the assembly position. Fit the companion flange onto the driving shaft first, when the companion flange has an interference hole. Align the keyways with their seats, insert the screws in the matching flange aligned holes and partially screw with their nuts, when the companion flange has a hole with no interference. Make the same operation for the driven side. After screwing all the bolts, tighten them by a dynamometrical wrench in a uniform and crosswise way. Check the tightening torque of all the fitting devices. Remove any cable or chain employed.

LUBRICATION

The universal shafts, the telescopic ones in particular, need to be fully greased. Pump lithium # 2 based grease into the grease nipples placed on the journal crosses and on the intermediate section of the universal shaft (for telescopic universal shafts), until grease leaks out of the seals. Do not over-pressurize bearings while greasing.

Figure 4.1

A pressure of 5 bar is strongly recommended. The telescopic universal shafts have to be greased in their fully compressed position, to avoid overfilling the splined shaft seat, which would compromise the length compensation operation.

Warning: lithium based grease is not compatible with other types of grease. Always check its compatibility with the grease producer.

LUBRICATION INTERVALS

Grease all the bearings and the splined shaft, if present, before starting to work and after 500 working hours. Next greasings shall be made every 30 days.

MAINTENANCE

Our universal shafts require very low maintenance. However, if you follow a regular maintenance program, you will ensure the best performances and the longest lifetime. Daily check tightening on the fitting devices and on the flange meshings.

If necessary, re-tighten them at the correct tightening torque. Regularly grease, as previously instructed.

Rolling Mill Application Data for Selection and Design

Fill in the boxes on the diagrams below for the following information:

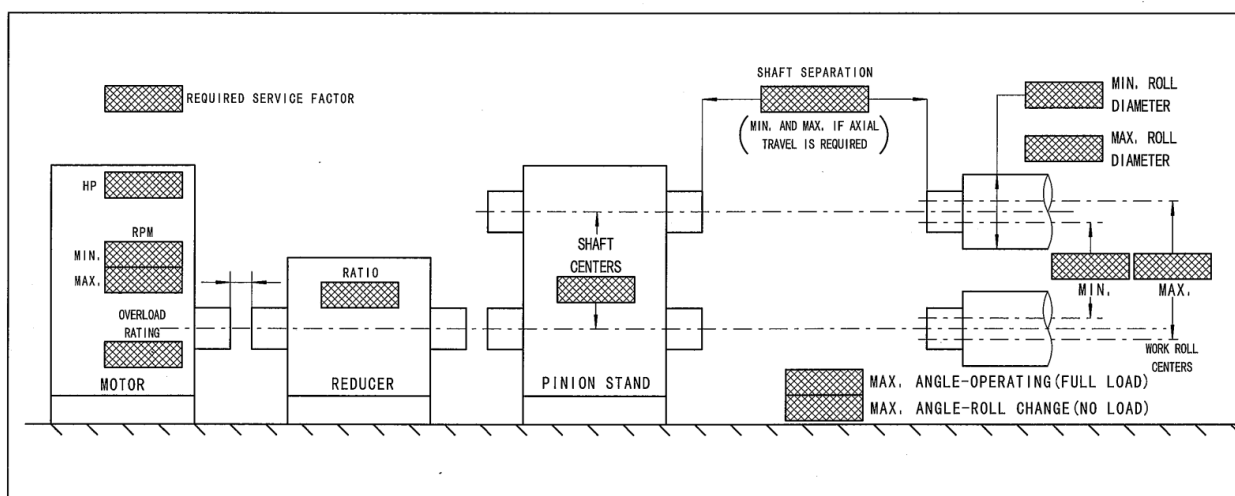

- 01. Motor horse power
- 02. Motor rpm
- 03. Required service factor
- 04. Operating rpm
- 05. Reducer ratio
- 06. Max. operating torque
- 07. Shaft separation
- 08. Pinion Centers
- 09. Min. Work Roll Diameter
- 10. Max. Work Roll Diameter

- 11. Min. Work Roll Centers – Operating
- 12. Max. Work Roll Centers – Operating
- 13. Max. Operating Angle (Full Load)
- 14. Max. Roll Change Angle (No Load)
- 15. Drive end bore and keyway
- 16. Bore Requirements
- 17. Driven end bore and keyway
- 18. Diameter limitations
- 19. Desired bearing lifetime
- 20. Ambient temperature

Comments or special conditions: _____

Note: if bolting to existing drive and driven flanges, please specify:

flange diameter: _____
 pilot diameter: _____
 bolt circle: _____
 number of bolts: _____
 keyway dimension: _____
